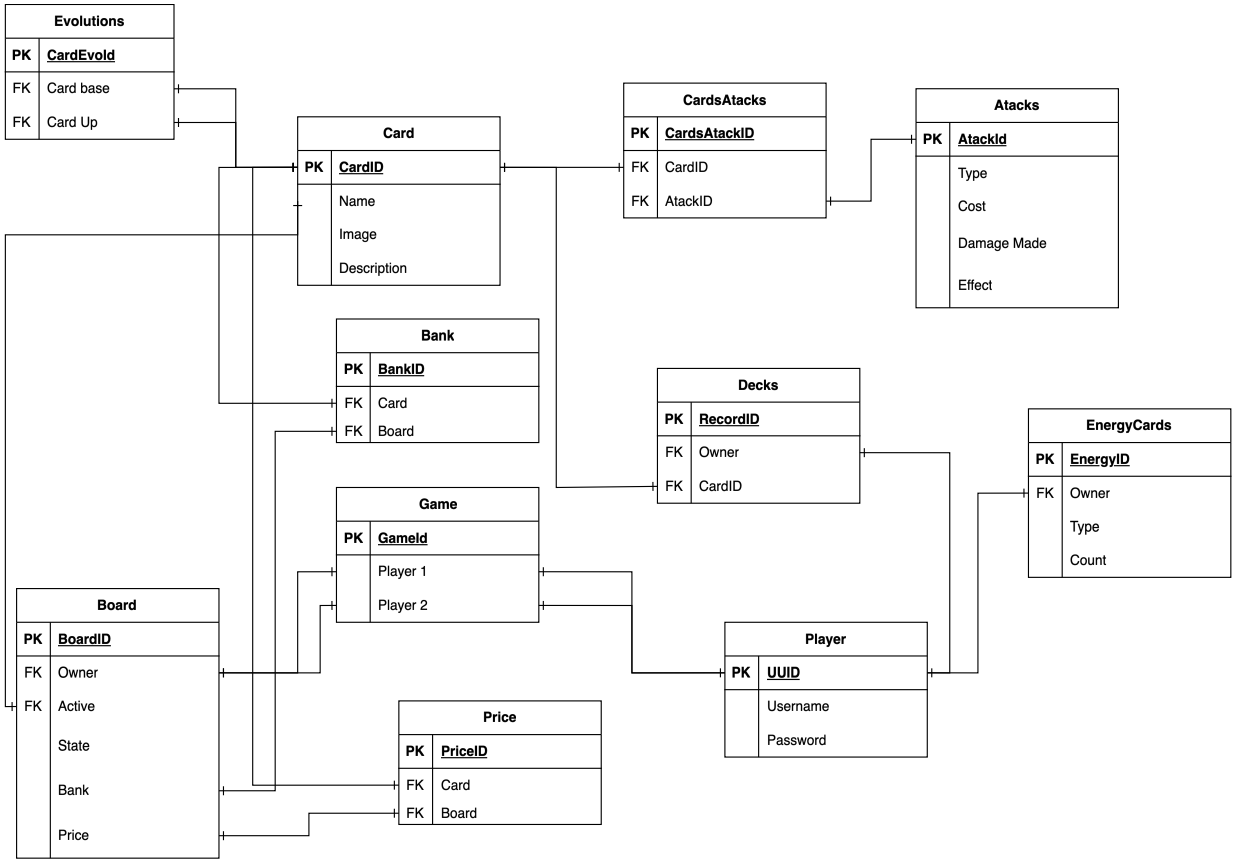
# Database design summary



We have a table called Card. This is the non-functional information. It can be joined with Attacks, which contain all the functional information. This includes information such as cost, damage, and whether this card has any effect when played.

Each player has a row on the board with game state information. It stores the owner of the board, the active card and its state (if an effect is applied), the reference to access the bank (of the player), and the player's *Price*. These are represented as rows of cards in the intermediary table of that name.

Also, Deck and Energy Cards are intermediary links that indicate what the player has.
